SPECT-CT and planar image of an ectopic mediastinal parathyroid adenoma

Jih-Fang Hsieh

CASE REPORT

A 50-year-old female was referred to our department for parathyroid scintigraphy due to incidental finding of hypercalcaemia. Tc-99m methyliodobenzylguanidine (MIBI) post-tracer injection early planar image at 20 minutes (arrow in Figure 1A) and delayed image at 2 hours (arrow in Figure 1B) show persistent focus of radiotracer accumulation at the middle of medial left chest. This focus was localized by single photon emission computed tomography-computed tomography (SPECT-CT) (Figure 2) in the left superior anterior mediastinum which is suggestive of an ectopic parathyroid adenoma. The patient underwent video-assisted thoracoscopic surgery (VATS) and pathology confirmed an ectopic parathyroid adenoma.

DISCUSSION

Anterior mediastinum is among one of the sites of an ectopic parathyroid adenoma. It has been reported in several studies that SPECT-CT offers the definite advantage of combined functional image and anatomic image in the accurate localization of a possible ectopic parathyroid gland. This case demonstrates the utility of SPECT-CT in optimal diagnosis in scintigraphy which combined anatomical and physiologic images [1–4].

Figure 1: Technetium-99m (Tc-99m) MIBI post-tracer injection early planar image at 20 minutes (A arrow) and delayed image at 2 hours (B arrow) show persistent focus of radiotracer accumulation at the middle of medial left chest. In addition, normal physiologic accumulation of the radiotracer is seen in the salivary glands, thyroid, and myocardium.

Figure 2: Axial, coronal, and sagittal fused SPECT-CT images demonstrate the focus of Tc-99m MIBI accumulation at the left side of the chest is localized at the left superior anterior mediastinum.
Conclusions

Single photon emission computed tomography-computed tomography should be considered a standard in scintigraphy for optimal imaging of ectopic parathyroid gland.
